

# Review Problems for Kinetics Unit

A bottle of hydrogen peroxide,  $\text{H}_2\text{O}_2$ , slowly decomposes to produce water and oxygen

The following data were recorded in an experimental study of the kinetics of this decomposition reaction (a small amount of  $\text{I}^-$  was added as a catalyst to make the reaction go faster).

Time (s)	$[\text{H}_2\text{O}_2]$ (M)	Time (s)	$[\text{H}_2\text{O}_2]$ (M)	Time (s)	$[\text{H}_2\text{O}_2]$ (M)
0	0.882	240	0.372	480	0.152
60	0.697	300	0.298	540	0.120
120	0.566	360	0.236	600	0.094
180	0.458	420	0.188	660	???

A graph of  $[\text{H}_2\text{O}_2]$  vs. time is shown here.

**Problem 1.** What is the average rate for the period in which the reaction is monitored?

**Answer.** The average rate is  $-\Delta[\text{H}_2\text{O}_2]/\Delta t$  for the time period in question; thus, the average rate in this case is

$$-\frac{(0.094 - 0.882)}{(600 - 0)} = 1.31 \times 10^{-3} \text{ M/s}$$

**Problem 2.** Estimate the instantaneous rate at  $t = 60$  s?

**Answer.** The instantaneous rate is the slope of the tangent to the curve of  $[\text{H}_2\text{O}_2]$  vs. time  $t = 60$  s. Using the data in the figure gives the rate as  $2.8 \times 10^{-3}$  M/s.

**Problem 3.** What is the rate law for this reaction, including the value of the rate constant?

**Answer.** Plotting  $\ln[\text{H}_2\text{O}_2]$  vs. time gives a straight line with a slope of  $0.00370 \text{ s}^{-1}$ ; thus, the reaction is first-order. You also could estimate half-lives to arrive at the same result.

**Problem 4.** The table shows ??? as the concentration of  $\text{H}_2\text{O}_2$  at 660 s. What is the missing value?

**Answer.** Here you can use the integrated rate law; thus

$$\ln[\text{H}_2\text{O}_2]_{660} = \ln(0.882) - (0.00370 \text{ s}^{-1})(660 \text{ s})$$

Solving gives the concentration of  $\text{H}_2\text{O}_2$  as  $7.67 \times 10^{-2} \text{ M}$ .

**Problem 5.** Suppose you have a solution of 3.6 M  $\text{H}_2\text{O}_2$ . How long will it take for the concentration to decrease to 0.25 M?

**Answer.** Again, we use the integrated rate law; thus

$$\ln(0.25) = \ln(3.6) - (0.00370 \text{ s}^{-1})t$$

which gives  $t$  as 720 s.

**Problem 6.** The concentrated  $\text{H}_2\text{O}_2$  we purchase is 3.6 M and comes with a warning that it needs to be kept refrigerated. Why do you think that warning is placed on the bottle?

**Answer.** Reactions go more slowly at lower temperatures. Cooling the peroxide ensures that it won't accidentally react too quickly; producing lots of  $\text{O}_2$  in a closed container could lead to an explosion.
